## LANDFALL FORECAST ERRORS

Listed below are the errors in predicting the points of landfall of the two storms which crossed the coastline of the United States in 1976. The errors are for the Official forecasts issued twenty-four hours prior to landfall time.

Storm	Landfall Day	Landfall Location	Landfall Forecast Error
Belle	August 10	Jones Beach, Long Island, N.Y.	30 miles
Dottie	August 20	Folly Beach, S.C.	5 miles

NATIONAL HURRICANE CENTER

TROPICAL CYCLONE FORECAST VERIFICATION 1976

The following tables contain verification statistics for the 1976 tropical cyclone forecasts. The track forecast errors, expressed in nautical miles are computed in the following way. The magnitude of the vector difference (measured along a great circle) between the forecast displacement for a given time period and the actual displacement taken from 'Best Track' is computed for each forecast. All forecasts for which a given cyclone maintains at least tropical storm intensity are verified. These results are then averaged and tabulated.

The errors in the initial positioning of storms are also computed. For a given forecast, this is simply the magnitude of the great circle distance between the operational initial position and the corresponding 'Track' initial position.

FROM: Harry E. Brown, Chief, Basic Weather Branch, FD/NMC

SUBJECT: Revision to "Report on the 1976 NOAA/NWS Hurricane Conference," December 20, 1976

Section C of the table attached to the original report showed the forecast displacement errors in nautical miles for NMC, NHC and the official forecasts. The original homogeneous sample was incomplete, but Dr. J. Pellissier has since provided the complete sample in the table attached to this note.

The complete verification shows a comparison between NMC and NHC more as had been anticipated; i.e., NHC is the better at 12 hours and NMC is the better at the longer ranges. Furthermore, the average errors are somewhat smaller.
